Summary

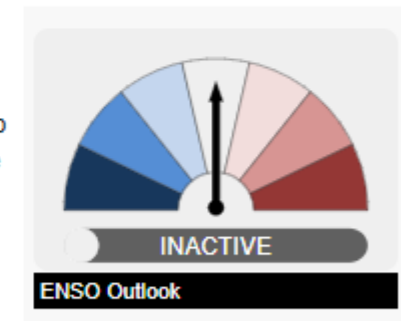

Sea surface

Southern Annular Mode positive, El Niño–Southern Oscillation neutral

The El Niño–Southern Oscillation (ENSO) continues at neutral levels. Climate model outlooks currently indicate this neutral phase will last at least until October.

Oceanic indicators of ENSO persist at neutral levels, with Pacific sea surface temperatures close to the long-term average across most of the equatorial region. Beneath the surface, temperatures are near-average, with slightly warmer than average waters across much of the sub-surface. Atmospheric indicators such as the Southern Oscillation Index (SOI) and cloud patterns are also close to average. Trade winds have been stronger than average in the far west, but near average elsewhere.

The Madden–Julian Oscillation (MJO) is over the Indian Ocean region. It is forecast to move eastwards across Australian longitudes over the coming fortnight. When the MJO is active over the eastern Indian Ocean and Australian longitudes at this time of year, above average rainfall is more likely over the [Maritime Continent](#) to Australia's north. Additionally, it typically acts to strengthen easterly winds on Queensland's tropical east coast and increase temperatures across tropical Australia.

Climate Model Summary for June to October 2021

Issued 12 May 2021 Next issue 15 June 2021

Australian climate is influenced by temperature patterns in the Pacific and Indian Oceans. This page provides information on Pacific Ocean outlooks for the coming six months based on a survey of international climate models.

Neutral El Niño-Southern Oscillation for winter

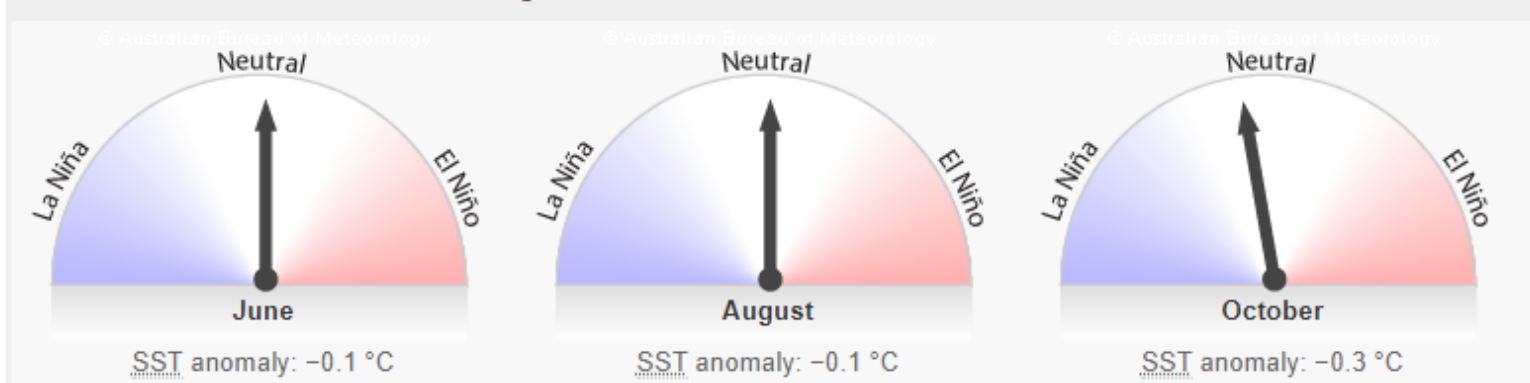

The El Niño-Southern Oscillation (ENSO) is neutral. Model outlooks (which forecast the oceanic component of ENSO) indicate the central tropical Pacific (NINO3.4) will remain at ENSO-neutral levels until at least early spring. A neutral ENSO state has little influence on the Australian climate.

The Indian Ocean Dipole (IOD) is currently neutral with most models favouring a neutral outlook for the end of autumn and early winter. Three out of the five models surveyed indicate the possibility of negative IOD thresholds being reached during winter and spring. Model accuracy is generally lower at this time of the year than at other times, so longer lead outlooks should be viewed with caution.
